

Point Feature Responses *before* using our Transformer Encoder

Point Feature Responses *after* using our Transformer Encoder

We randomly select *six* testing examples (patches) to visualize the learned point features in a heat-map view.

We normalize the channels of learned features to calculate the response for each point, where the **blue color** represents a **low response** while the **red color** denotes a **high response**.

By using our Transformer, higher attention is assigned to cover a complete outline of each patch and retain fine-grained details in complex local areas such as the convex parts.
